

Anthromathematics: Mathematics of the Third Millennium

Syed Arif Kamal*

Subject Committee for Physical Education, Health and Sport Sciences, National Testing Service Pakistan
SF-Growth-and-Imaging Laboratory, Anthromathematics Group
Department of Mathematics and the NGDS Pilot Project,
University of Karachi; profdrakamal@gmail.com

The speaker described activities of the Anthromathematics Group, with a brief introduction to mathematical models of brain (covariant, generalized coupling, covariant generalized coupling and mathematical definition of brain death), heart (standing wave), spinal column (static and dynamic) and physical growth of children (ICP, KFA and KJK). *Anthromathematics* was defined as the mathematics of human body sizes, forms, proportions and structures. The term was first introduced on March 22, 2010 by the speaker during the *First National Conference on Mathematical Sciences* held at University of Karachi. Third-millennium challenges required that the sciences of *anthropology* (study of human being) and *anthropometry* (measurement of human being) be transformed to *anthromathematics* through ideas from mathematics, e. g., mathematical equations employed to approximate human body form (*analysis* — formulae for surface area and volume of human body), discrete structures recognized in the anatomy and the physiology of human body (*algebra* — brain death defined, mathematically, through study of group structure), invariance under deformations discovered (*topology* — spinal column deformed because of scoliosis, kyphosis or lordosis, studied by static and dynamic models), properties of numbers studied (*number theory* — numbers giving height, weight and other anthropometric measures) as well as inferences analyzed (*logic* — upper limits of optimal weight-for-height). To elaborate the point further, an *anthropometrist* is supposed to take heights, but an *anthromathematician*, not only, must measure heights, but also, determine accuracy, precision and reproducibility of the techniques used, while planning the session, align the scale, ascertain that the surface is level, check the equipment against agreed-upon standards at the start of each session and, finally, estimate consistency of collected data at the end of every session. The focus, then, shifted towards mathematical model of physical examination. Mathematical concepts used in the physical examination were elaborated: (i) *symmetry* (left-right) in the body shape, size, number of limbs (fingers, toes), anatomical landmarks (scapulae, body triangles, spinal dimples, shoulder/neck line, knee joints, in the context of scoliosis indicators) — asymmetry as the first indicator of breast cancer, (ii) *inverse problem* — determining properties of source from the properties of field (e. g., auscultation using stethoscope; the sound recorded from heart, lungs or stomach comes through the body tissue and skin, which must be accounted for), radiative-transfer equation was used to compute intensity, when source function was known (proper interpretation of X-ray intensity in CT scan using radiative transfer equation brought Nobel Prize in medicine, basis of clinical thermograms), (iii) *precedence graph* — some checks have to be performed before the others, overlooking this might effect, adversely, on patient's health (e. g., examination of resting heart to be performed before treadmill testing, or hernia check must precede cardiac function testing in the squatting position), (iv) *influence graph* — some procedures influence certain portions of the examination (e. g., running influenced blood pressure and heart rate). There is, therefore, a need to devise protocols of examination in such a way that interacting procedures are performed in a laid-down sequence, or during separate sessions. These protocols must indicate which procedures must precede the others and which ones could be performed concurrently (e. g., cardiac function in the standing position and check for undescended testicles). The techniques used in physical examination by a medical professional consist of auscultation, percussion and olfaction (all three employ *inverse problem*), inspection (employs symmetry) and palpation (employs properties of material, body temperature). 3 new branches of mathematics, 'anthroalgebra' (study of body structures in anatomy through mathematical concepts), 'anthrogeometry' (study of heights and curvatures on the human body using techniques of stereophotogrammetry) and 'anthrodynamics' (derived from anthromathematics, with ideas from biology, computer science, mathematics and physics, powered through dynamical-system analysis) were introduced in this seminar. Combined with 'anthrotopology' introduced on December 27, 2012, these 4 sub-branches of anthromathematics should enhance the applicability of this branch of mathematics.

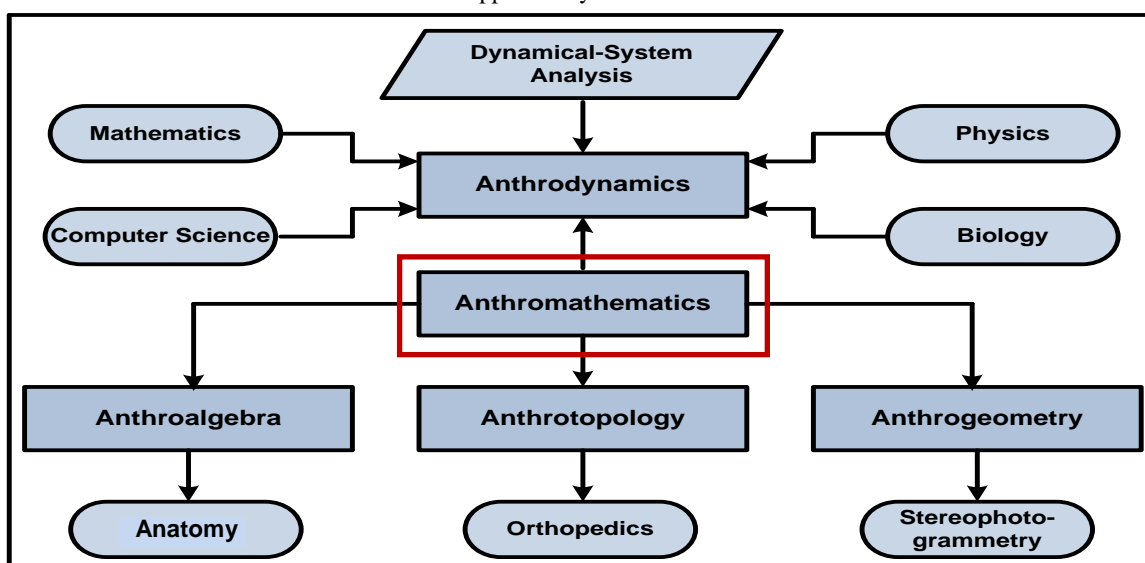

Fig. 1. From 'anthropometry' to 'anthrodynamics': a bridge through 'anthromathematics'

Keywords: Anthroalgebra • Anthrodynamics • Anthrogeometry • Children • Height • Physical examination • Weight

Conflict of Interest Statement: No potential conflict of interest was identified for this work.

Grant Sponsor: Dean's (Science) Research Grant, University of Karachi, number DFRS/2009

Research Ethics: The NGDS Pilot Project initiated after *Institutional Review Process* and conducted in compliance with ethical and human-rights standards.
